Do CPOs Need to Learn How to Code?

Paul Ohm (Georgetown), Joseph Lorenzo Hall (CDT)
Q: Do CPOs need to know how to code?

A: No.
Q: Do CPOs need to know how to code?

A: No. (but can’t hurt)
Introduction
Paul Ohm
Georgetown Law
Professor of Law

- Technical background
- Worked at DOJ/CCIPS (trial attorney) and FTC (policy advisor)
- Teaches “The Technology of Privacy” to law students
- Author of the only law review article that is also a working computer program: 54 Villanova Law Review 117
Joseph Lorenzo Hall
CDT
Chief Technologist

- Hard science background (astrophysics)
- Technical background (“hacking” voting machines)
- Raised by policy-focused lawyers (P. Samuelson, D. Mulligan), computer scientists (D. Wagner, E. Felten) and philosophers (H. Nissenbaum)
Goals for this session

Our goal: an interactive discussion around the technical insight C-level privacy and policy professionals must have to do their jobs well

We cannot possibly “make you technical” in the time we have

However, we can give you a flavor for places to do further research

And we can definitely give you insight into particular questions that bug you
Our Approach

Internet-centric

Specific technical concepts connected to real legal and policy conflicts

For each example:

- The benefits of “n++” knowledge
- Highlight misconceptions from “n” knowledge
Good decisions increasingly need technical input

Rep. Chaffetz discussing SOPA and Sandia National Labs letter

(open video below in Chrome)

Let’s start with you!

What kinds of technical issues do you encounter on a regular basis that you’d like to get smarter about?

What do you secretly not understand as well as people think you do?
Outline

Basic layered framework of networks and computers

Examples:
- Internet Protocol addresses
- Source vs. binary code
- Software vulnerabilities
- HTTP/HTTPS (web)
- Crypto 101

“The Playbook”

Acquiring Skills: Get your hands dirty!
A Framework
Network Model
Computer Model (or “software stack”)
Examples
Basic Internet Architecture – IP addresses

What they are: 141.161.191.223 or 104.20.11.17

How they are allocated

“Uniqueness”

Network Address Translation (NAT)

Log files as 21st century crime scene

69.41.16.195 — — [22/Oct/2015:16:35:36 -0700] "GET /drugs/cocaine/buy.cgi HTTP/1.1" 200 4242 "-" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_5) AppleWebKit/601.1.56 (KHTML, like Gecko) Version/9.0 Safari/601.1.56"
Basic Internet Architecture – DNS

Humans would rather remember www.cdt.org than 104.20.11.17 (IP Address)

The Domain Name System is a hierarchical, distributed resource for looking up IP addresses of domains

DNS can be an Internet chokepoint

privacy implications

Relevant to SOPA/PIPA

filtering of DNS traffic
Source Code vs Executable (Binary) Code

source code is compiled into object code which is then linked to libraries to produce executable (binary) code

Most software is distributed in binary

Open source software distributes source, generously licensed

-Reverse engineering
-White vs black box testing
-Static analysis/fuzzing
Software vulnerabilities and Safer code

Software has bugs!

Heartbleed was serious, due to a bug in OpenSSL

Allowed one to extract memory from 17% of trusted servers around the world!
Software vulnerabilities and Safer code

Data validation at the heart of heartbleed

Type safety and emerging coding standards help avoid these problems
Protocols - HTTP/HTTPS

HTTP is the protocol of the web (hypertext)

HTTP URLs specify location on the web: http://www.cdt.org/

Structured set of message exchanges that result in the source code for a web page

Browsers then display

GET /index.html HTTP/1.1
Host: www.att.com

... Request web page

HTTP/1.1 200 OK
Content-Type: text/html

... Send web page
Protocols - HTTP/HTTPS

HTTPS is the *secure* version of HTTP

Authenticated and encrypted

Relies on SSL (sic) certificates

SSL is old, broken; TLS is the new hotness
Protocols - HTTP/HTTPS

Increasing use of HTTPS since Snowden revelations

However, general recognition that integrity just as important as confidentiality

- Technical standards (IETF, W3C, IEEE)
- .gov HTTPS-Only by end of 2016
- Major content (news, video), advertising
- Browsers “deprecating” HTTP
Crypto 101: What’s the point?

*Confidentiality* - only authorized parties can access information

*Authentication* - validation of a credential as identification of source

*Integrity* - information has not been modified (e.g., between sender/receiver)

*Non-repudiation* - cannot deny having encrypted information
Crypto 101: Symmetric cryptography

Works like a lock in the real world: Same key used to unlock and lock (decrypt and encrypt)

However, distributing the key then becomes the hard problem!
Crypto 101: Asymmetric cryptography

Works unlike locks in the real world: Different key for lock/unlock

Solves the key distribution problem: can share the locking key (the “public key”)

But keep the unlocking key (the “private key”) super-secret!
Crypto 101: Hashes and Signatures

![Diagram showing input, hash function, and hash value for two different inputs using SHA-1 hash function.](image)

**Figure 17: Hash Function**
Crypto 101: Hashes and Signatures
Crypto 101: Certificate Authorities/PKI

PKI = Public Key Infrastructure

wraps public key in cryptographic signature to produce “certificate”

a certificate is simply the result of:

a trusted entity (a “certificate authority”)
vouching for/attesting to the fact that
a given named entity (“Joseph Hall”, “josephhall.org”)
possesses the secret key that corresponds to the private key.
“The Playbook”
Analogies

“Her eyes were like two brown circles with two big black dots in the center.” (Russell Beland, Springfield)

“He was as tall as a six-foot-three-inch tree.” (Jack Bross, Chevy Chase)
